Compare group means using analysis of variance

Aldrin in the Wolf River

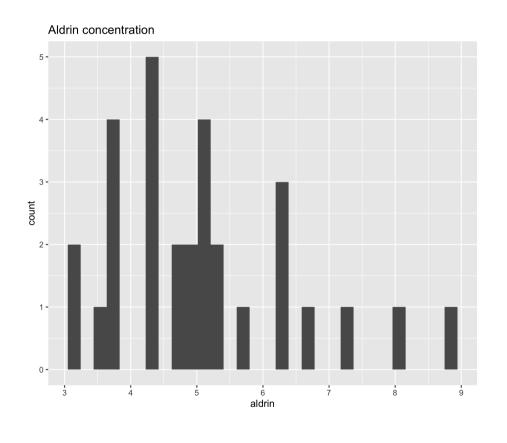

- The Wolf River in Tennessee flows past an abandoned site once used by the pesticide industry for dumping wastes, including chlordane (pesticide), aldrin, and dieldrin (both insecticides).
- These highly toxic organic compounds can cause various cancers and birth defects.

Aldrin in the Wolf River

The standard methods to test whether these substances are present in a river is to take samples at six-tenths depth.

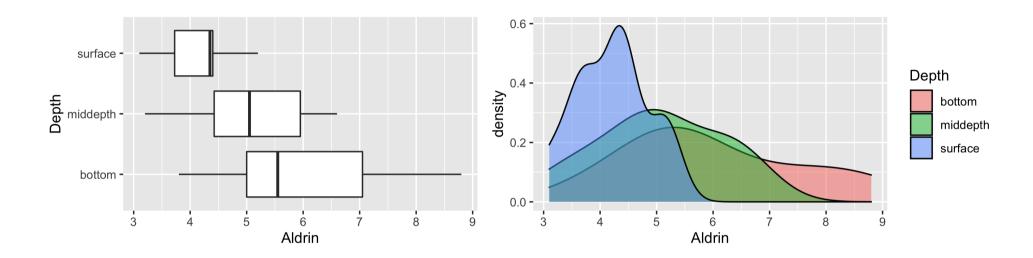

These compounds are denser than water and their molecules tend to stick to particles of sediment, they are more likely to be found in higher concentrations near the bottom than near mid-depth.

Is there a difference between the mean aldrin concentrations among the three depth levels?

Aldrin by depth

depth	n	mean	sd
bottom	10	6.04	1.579
middepth	10	5.05	1.104
surface	10	4.20	0.660

So far, we have used a **quantitative** predictor variable to understand the variation in a quantitative response variable.

Now, we will use a **categorical (qualitative)** predictor variable to understand the variation in a quantitative response variable.

Notation

- K is number of mutually exclusive groups. We index the groups as $i=1,\ldots,K$.
- n_i is number of observations in group i
- $n=n_1+n_2+\cdots+n_K$ is the total number of observations in the data
- y_{ij} is the j^{th} observation in group i, for all i,j
- μ_i is the population mean for group i, for $i = 1, \dots, K$

Using ANOVA to compare means

- Question of interest Is the mean value of the response y the same for all groups, or is there at least one group with a significantly different mean value?
- To answer this question, we will test the following hypotheses:

 $H_0: \mu_1 = \mu_2 = \cdots = \mu_K$

 H_a : At least one μ_i is not equal to the others

What's happening...

 $H_0: \mu_1 = \mu_2 = \dots = \mu_K$

 H_a : At least one μ_i is not equal to the others

- If the sample means are "far apart", " there is evidence against H_0
- We will calculate a test statistic to quantify "far apart" in the context of the data

Analysis of Variance (ANOVA)

Main Idea: Decompose the total variation in the data into the variation between groups (model) and the variation within each group (residuals)

$$\sum_{i=1}^{K} \sum_{j=1}^{n_i} (y_{ij} - \bar{y})^2 = \sum_{i=1}^{K} n_i (\bar{y}_i - \bar{y})^2 + \sum_{i=1}^{K} \sum_{j=1}^{n_i} (y_{ij} - \bar{y}_i)^2$$

If the variation between groups is significantly greater than the variation within each group, then there is evidence against the null hypothesis.

ANOVA table

term	df	sumsq	meansq	statistic	p.value
depth	2	16.961	8.480	6.134	0.006
Residuals	27	37.329	1.383		

Total variation

term	df	sumsq	meansq	statistic	p.value
depth	2	16.961	8.480	6.134	0.006
Residuals	27	37.329	1.383		

Total variation: variation between and within groups

$$SS_{Total} = 16.961 + 37.329 = 54.290$$

$$DF_{Total} = 2 + 37 = 29$$

$$s_y^2 = \frac{SS_{Total}}{DF_{Total}} = \frac{54.290}{29} = 1.872$$

Between variation

term	df	sumsq	meansq	statistic	p.value
depth	2	16.961	8.480	6.134	0.006
Residuals	27	37.329	1.383		

Between variation: variation in the group means

$$SS_{Retween} = 16.961$$

$$DF_{Between} = 2$$

$$MS_{Between} = \frac{SS_{Between}}{DF_{Between}} = \frac{15.961}{2} = 8.480$$

Within variation

term	df	sumsq	meansq	statistic	p.value
depth	2	16.961	8.480	6.134	0.006
Residuals	27	37.329	1.383		

Within variation: variation within each group

$$SS_{Within} = 37.329$$

$$DF_{Within} = 27$$

$$MS_{Within} = \frac{SS_{Within}}{DF_{Within}} = \frac{37.329}{27} = 1.383$$

Using ANOVA table to test difference in means

term	df	sumsq	meansq	statistic	p.value
depth	2	16.961	8.480	6.134	0.006
Residuals	27	37.329	1.383		

 $H_0: \mu_1 = \mu_2 = \mu_3$

 H_a : At least one depth level has μ_i that is not equal to the others

Using ANOVA table to test difference in means

term	df	sumsq	meansq	statistic	p.value
depth	2	16.961	8.480	6.134	0.006
Residuals	27	37.329	1.383		

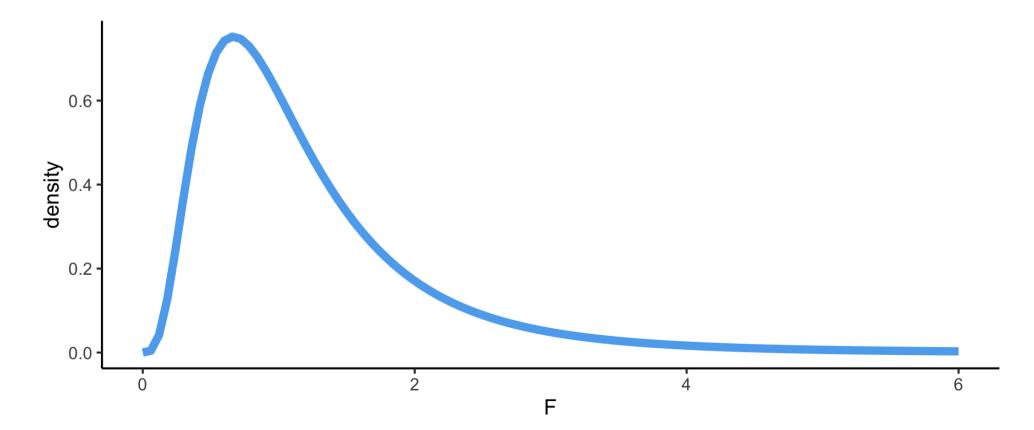

Test statistic: Ratio of between group and within group variation

$$F = \frac{MS_{Between}}{MS_{Within}} = \frac{8.480}{1.383} = 6.134$$

Calculate p-value

Calculate the p-value using an F distribution with K-1 and n-K degrees of freedom

Using ANOVA table to test difference in means

term	df	sumsq	meansq	statistic	p.value
depth	2	16.961	8.480	6.134	0.006
Residuals	27	37.329	1.383		

P-value: Probability of observing a test statistic at least as extreme as *F* Stat given the group means are equal

The p-value is very small (≈ 0), so we reject H_0 . The data provide sufficient evidence that at least one depth level has a mean aldrin concentration that differs from the others.

Assumptions for ANOVA

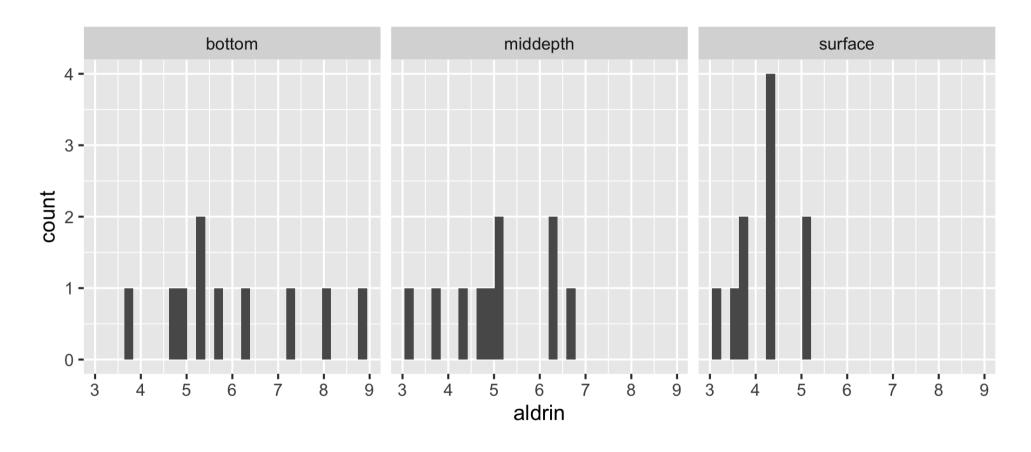

Assumptions for ANOVA

- **1** Normality: $y_{ij} \sim N(\mu_i, \sigma^2)$
- **2** Constant variance: The population distribution for each group has a common variance, σ^2
- Independence: The observations are independent from each other
- This applies to observations within and between groups

For ANOVA, we can typically check these assumptions in the exploratory data analysis

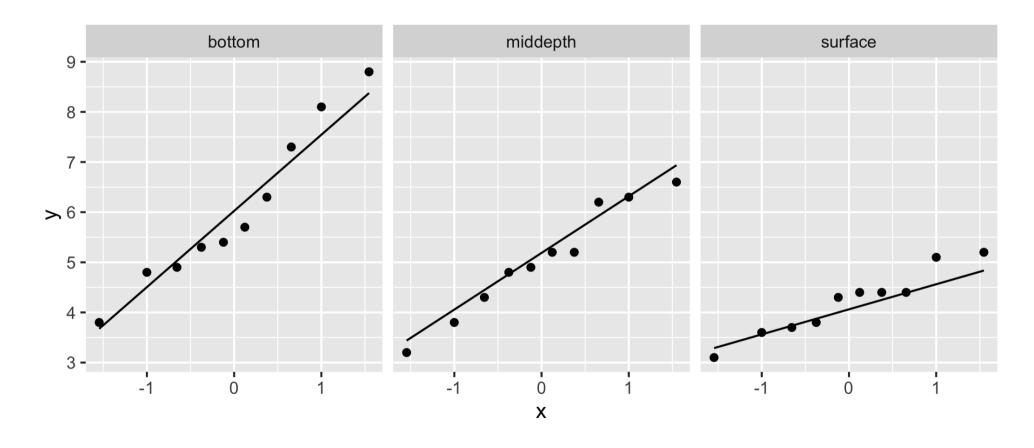

Checking Normality

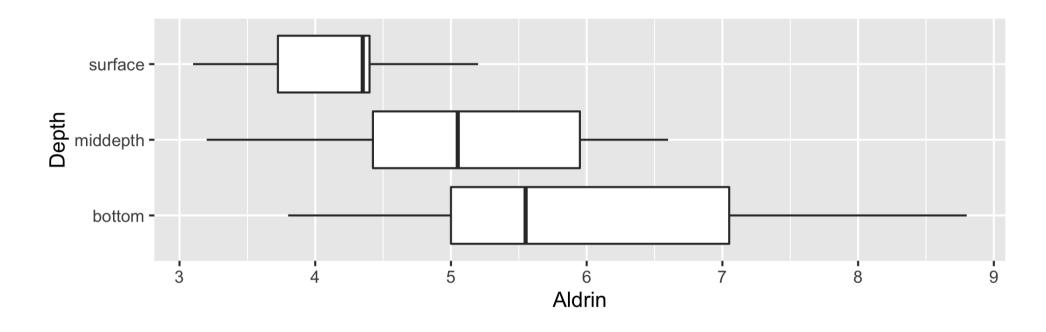

Checking Normality

Checking constant variance

The maximum standard deviation is about 2.4 times the smallest one. This is OK given the small sample size.

Checking independence

☑ Based on what we know about the study, we have no reason to believe that the aldrin concentrations are not independent of each other.

Robustness to Assumptions

- Normality: $y_{ij} \sim N(\mu_i, \sigma^2)$
 - ANOVA relatively robust to departures from Normality.
 - Concern when there are strongly skewed distributions with different sample sizes (especially if sample sizes are small, < 10 in each group)
- Independence: There is independence within and across groups
 - If this doesn't hold, should use methods that account for correlated errors

Robustness to Assumptions

- Constant variance: The population distribution for each group has a common variance, σ^2
 - Critical assumption, since the pooled (combined) variance is important for ANOVA
 - General rule: Satisfied if $SD_{max}/SD_{min} \le 2$. OK if this is somewhat > 2 when sample sizes are small.

Recap

Used ANOVA to compare means across groups
